AfriSAR

Mission reveals clues about global changes

By Maria-José Viñas
 NASA's Earth Science News Team

Gabon, a Central African country slightly smaller than the state of Colorado, is home to one of the most pristine rainforests on the planet. During the two-week-long NASA campaign, a collaboration with a European Space Agency (ESA) mission called AfriSAR, researchers collected measurements of plant mass, distribution of trees, shrubs and ground cover, and diversity of plant and animal species – not only from Gabon's rainforest but also from the country's wetlands, mangrove forests and savanna.

ESA launched the first part of the AfriSAR field campaign in Gabon in July 2015, when teams led by the French National Aerospace Research Center collected radar and field measurements of the country's forests. NASA and the German Aerospace Center (DLR) joined the second

leg of the campaign.

The data will help prepare for and calibrate four current and upcoming spaceborne missions for NASA, ESA and DLR that aim to, among other goals, better gauge the role of forests in Earth's carbon cycle.

“One of the questions we're really interested in at NASA is balancing

the global carbon budget,” said Lola Fatoyinbo, a research scientist at NASA’s Goddard Space Flight Center in Greenbelt, Maryland, and lead of NASA’s contribution to the AfriSAR campaign. “We know how much carbon dioxide is being emitted into the atmosphere by fossil fuel emissions, but we don’t have a good estimate of how much carbon is being taken up from the atmosphere and where it’s stored – we think that forests absorb about a quarter of all these emissions, but we need better studies of forest biomass to confirm this.

“With AfriSAR, we’re getting very accurate measurements of the 3-D structure of an ecosystem that is representative of the larger Congo Basin rainforest and of tropical forests in general, and this is going to allow us to get a better grip on how much carbon is stored in these ecosystems,” Fatoyinbo said.

Gabon’s forest is part of the Congolian tropical forests, altogether the second largest rainforest in the world after the Amazon. About 85 percent of the country’s land is forest: only about 1.5 million people live there.

“The forests in Gabon are special: they are rich in plants and animals, but empty of people and intact in most places,” said Sassan Saatchi, a senior scientist from NASA’s Jet Propulsion Laboratory in Pasadena, California. He is part of the NASA AfriSAR team that operates the Uninhabited Aerial Vehicle Synthetic Aperture Radar (UAVSAR). More information on UAVSAR is located at: <http://uavsar.jpl.nasa.gov>. The other NASA group participating in AfriSAR, led by Goddard scientist Bryan Blair, is in charge of the Land, Vegetation, and Ice Sensor (LVIS) instrument.

During the AfriSAR campaign, the UAVSAR system that is mounted in a pod beneath a C-20A aircraft from NASA Armstrong, flies at about 40,000 feet altitude. LVIS flies at 28,000 feet onboard a B-200 airplane from NASA’s Langley Research Center in Hampton, Virginia. Both systems send out a series of radio or light wave pulses and record the time and strength of the reflected signals. LVIS, which points directly below the aircraft, is able to determine the height of the canopy and ground and the 3-D canopy structure by measuring how long it takes the signals to bounce back. UAVSAR looks to the left side of the aircraft and uses data from two or more specially designed flight paths separated by 60 feet to 600 feet to extract canopy 3-D structure and ground topography.

“LVIS studies the vertical structure of the forests by measuring the elevation of everything the photons hit: the top of the canopy, all of the leaves and branches and finally the ground” said Blair, principal investigator and developer of LVIS. “In tropical forests, the challenge is to get the laser pulse all the way to the ground because the whole canopy is closed; there are very few holes for the photons to get through.”

The data collected by LVIS will help calibrate and validate the information gathered by UAVSAR over the same targets, and vice versa. The two datasets will also be compared to the airborne radar measurements that ESA and DLR are compiling during their current campaigns in Gabon.

“Whenever you are studying a complex system like a tropical forest no one instrument provides all the information needed to understand it,” said Scott Hensley, a senior research specialist at JPL. “Collecting data from multiple sensors allows for the extraction of complementary information and to cross calibrate various data products obtained from the instruments.”

Finally, AfriSAR’s ground teams from Goddard and JPL are collecting several types of field measurements, such as tree width, forest structure and soil moisture, which will complement and refine the data gathered from the air.

Both NASA airborne instruments are test beds for future space missions. LVIS is the precursor to the Global Ecosystem Dynamics Investigation lidar (GEDI), a powerful laser altimeter that will be installed on the International

Space Station in the near future to measure forests in 3-D. UAVSAR will help develop the NASA-ISRO Synthetic Aperture Radar, or NISAR, a joint U.S. and Indian radar-based satellite mission set to launch in 2020. In turn, the European space agencies' radar measurements in Gabon are aimed to prepare for ESA's BIOMASS satellite mission, which will deploy in 2020. DLR will also compare the data to the measurements collected by its TanDEM-X satellite constellation, launched in 2010.

Furthermore, the forest data gathered in Gabon might help to inform policymakers working on climate mitigation and forest conservation policies, Saatchi said.

AfriSAR is NASA's first collaboration with Gabon's young space agency, AGEOS, and also is one of the few large international campaigns in Africa since NASA's participation in a hydrological study of the Sahel in the 1990s.
